

# Curvature of nodal lines at nodal-Neumann line intersections

## Curvature of nodal lines at nodal-Neumann line intersections

Intersection points (green balls and enumerated) of Neumann lines (purple) and nodal lines (gray); left: Neumann domains (blue+red and enclosed by Neumann lines) and Neumann lines (purple), nodal lines (gray), nodal domains (blue or red and enclosed by nodal lines), saddles (yellow), extrema (red,blue); right: curvature (y-axis) of a specific nodal line (supporting the green intersection balls) parametrized by its arc length (x-axis) starting at a cyan ball and ending at a purple ball. The python program producing the plots is based on <https://github.com/inclement/neumann> (A. Taylor).

All three plots correspond to eigenfunctions of the Laplacian on the flat torus corresponding to the degenerate eigenvalues  $\lambda = 41, 17, 17$  (in chronological order). Notice that the point 3 in the second plot and the points 19, 6 in the third plot don't satisfy the local extremal property for the curvature at nodal-Neumann line intersections. The first plot exhibits such an behavior being 'closer' to an separable eigenfunction.
